

A vibrant, cartoon-style illustration of a South Park town square. In the foreground, three boys (Eric Cartman, Kenny McCormick, and Kyle Broflovski) are smiling. Behind them, a large crowd of diverse characters, including Mr. Garrison, Mr. Mackey, and various other townsfolk, is gathered. In the background, there are snow-capped mountains, a hot air balloon, a helicopter, and a red devil-like creature. A large, tilted brown banner is superimposed over the middle of the scene.

Category-based routing in social networks

Denitsa Dobрева

Overview

- Small-world phenomenon
- Definitions and routing algorithm
- Building categories
- Summary

Part 1

Small-world phenomenon

Small world phenomenon

- The phenomenon of elements being perceived to be very far away but are only at a distance of few hops
- The experience of meeting a complete stranger and finding out you share a mutual friend
 - “It’s a small world” ... we say

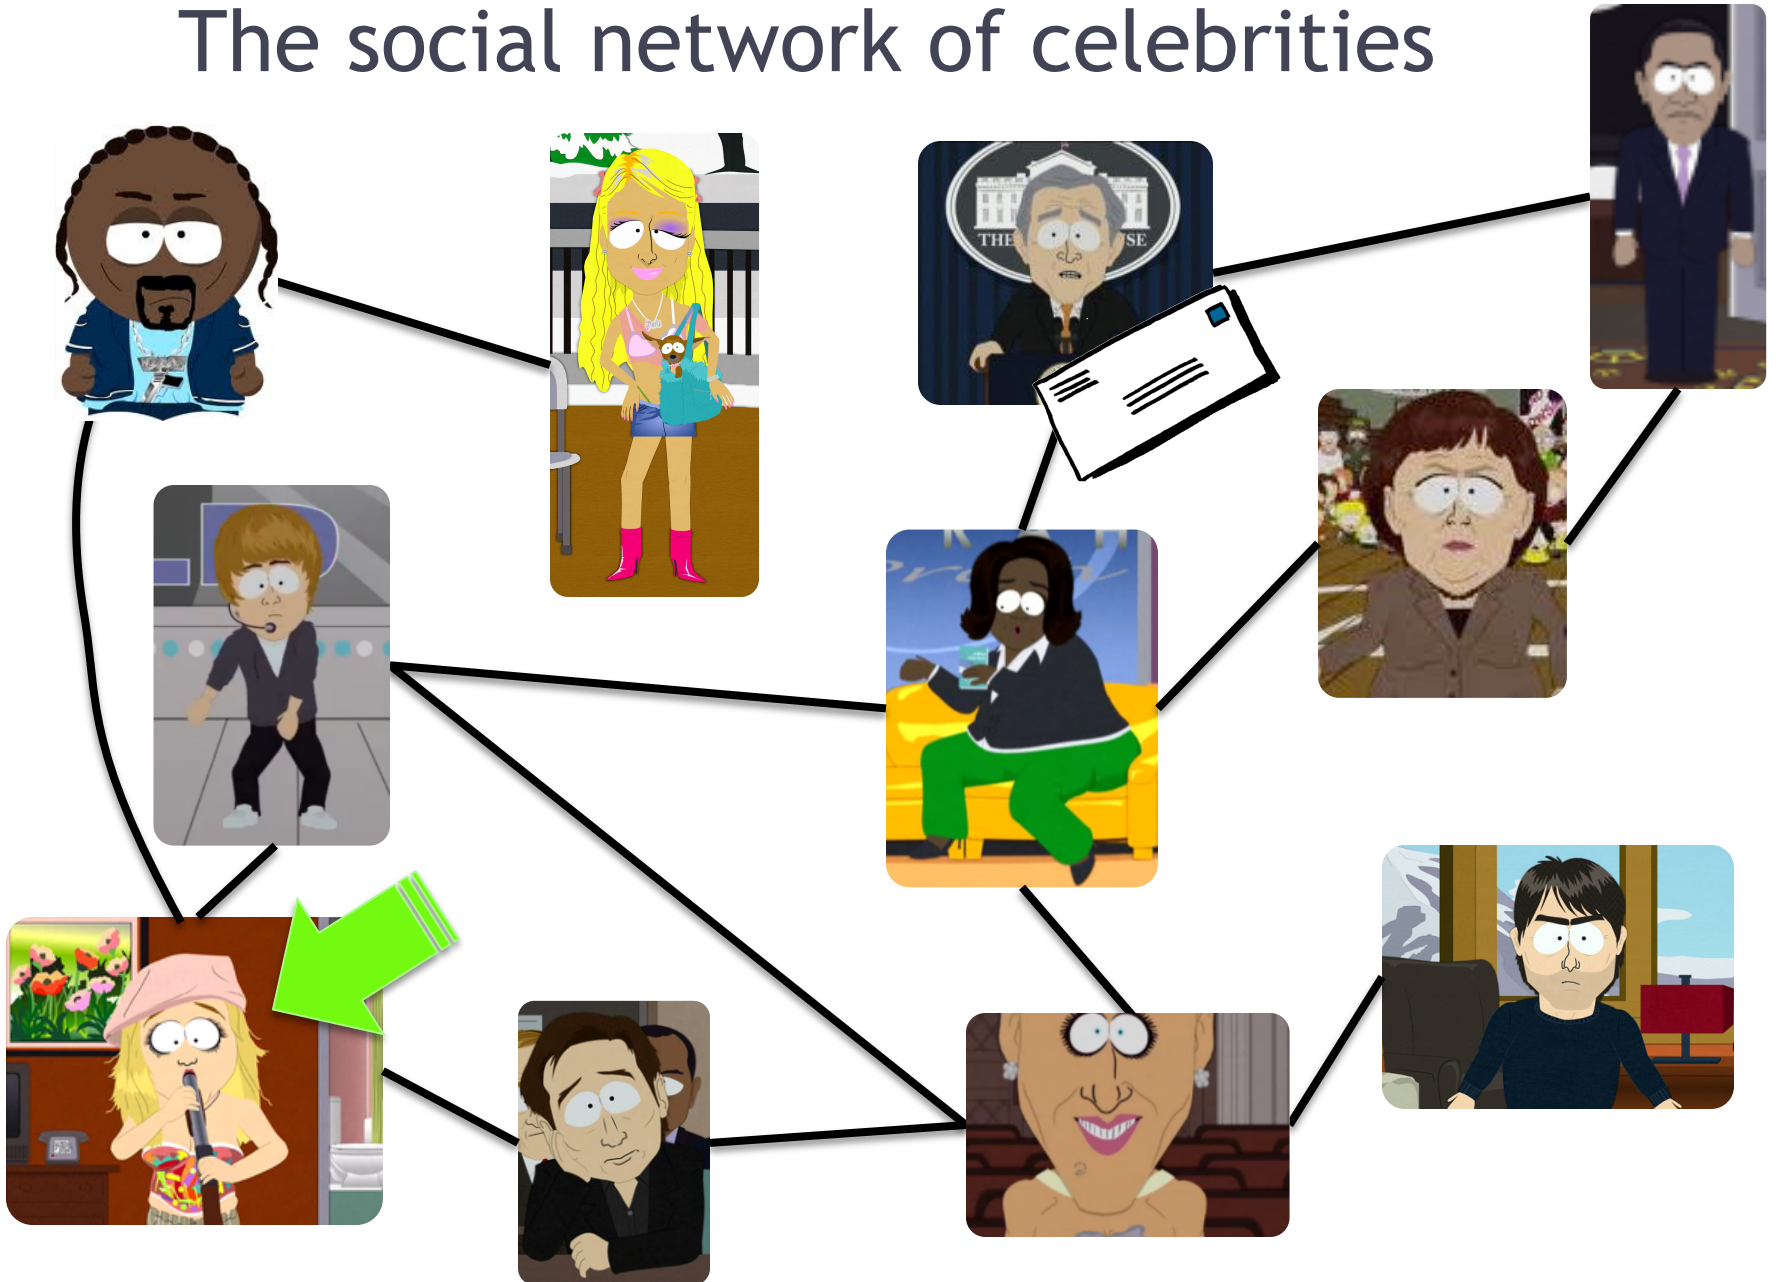

The notion of the small world phenomenon

- Milgram's experiment from the 1960's
 - Given: Social network
 - Idea: How many jumps are needed to reach a random person?
 - Starters: Random people from Nebraska
 - Target: Person, who lived in Massachusetts and worked in Boston
 - Known: Basic information about the target
 - Rule: Send to a people known on first name basis
- Routing using only local information and simple facts

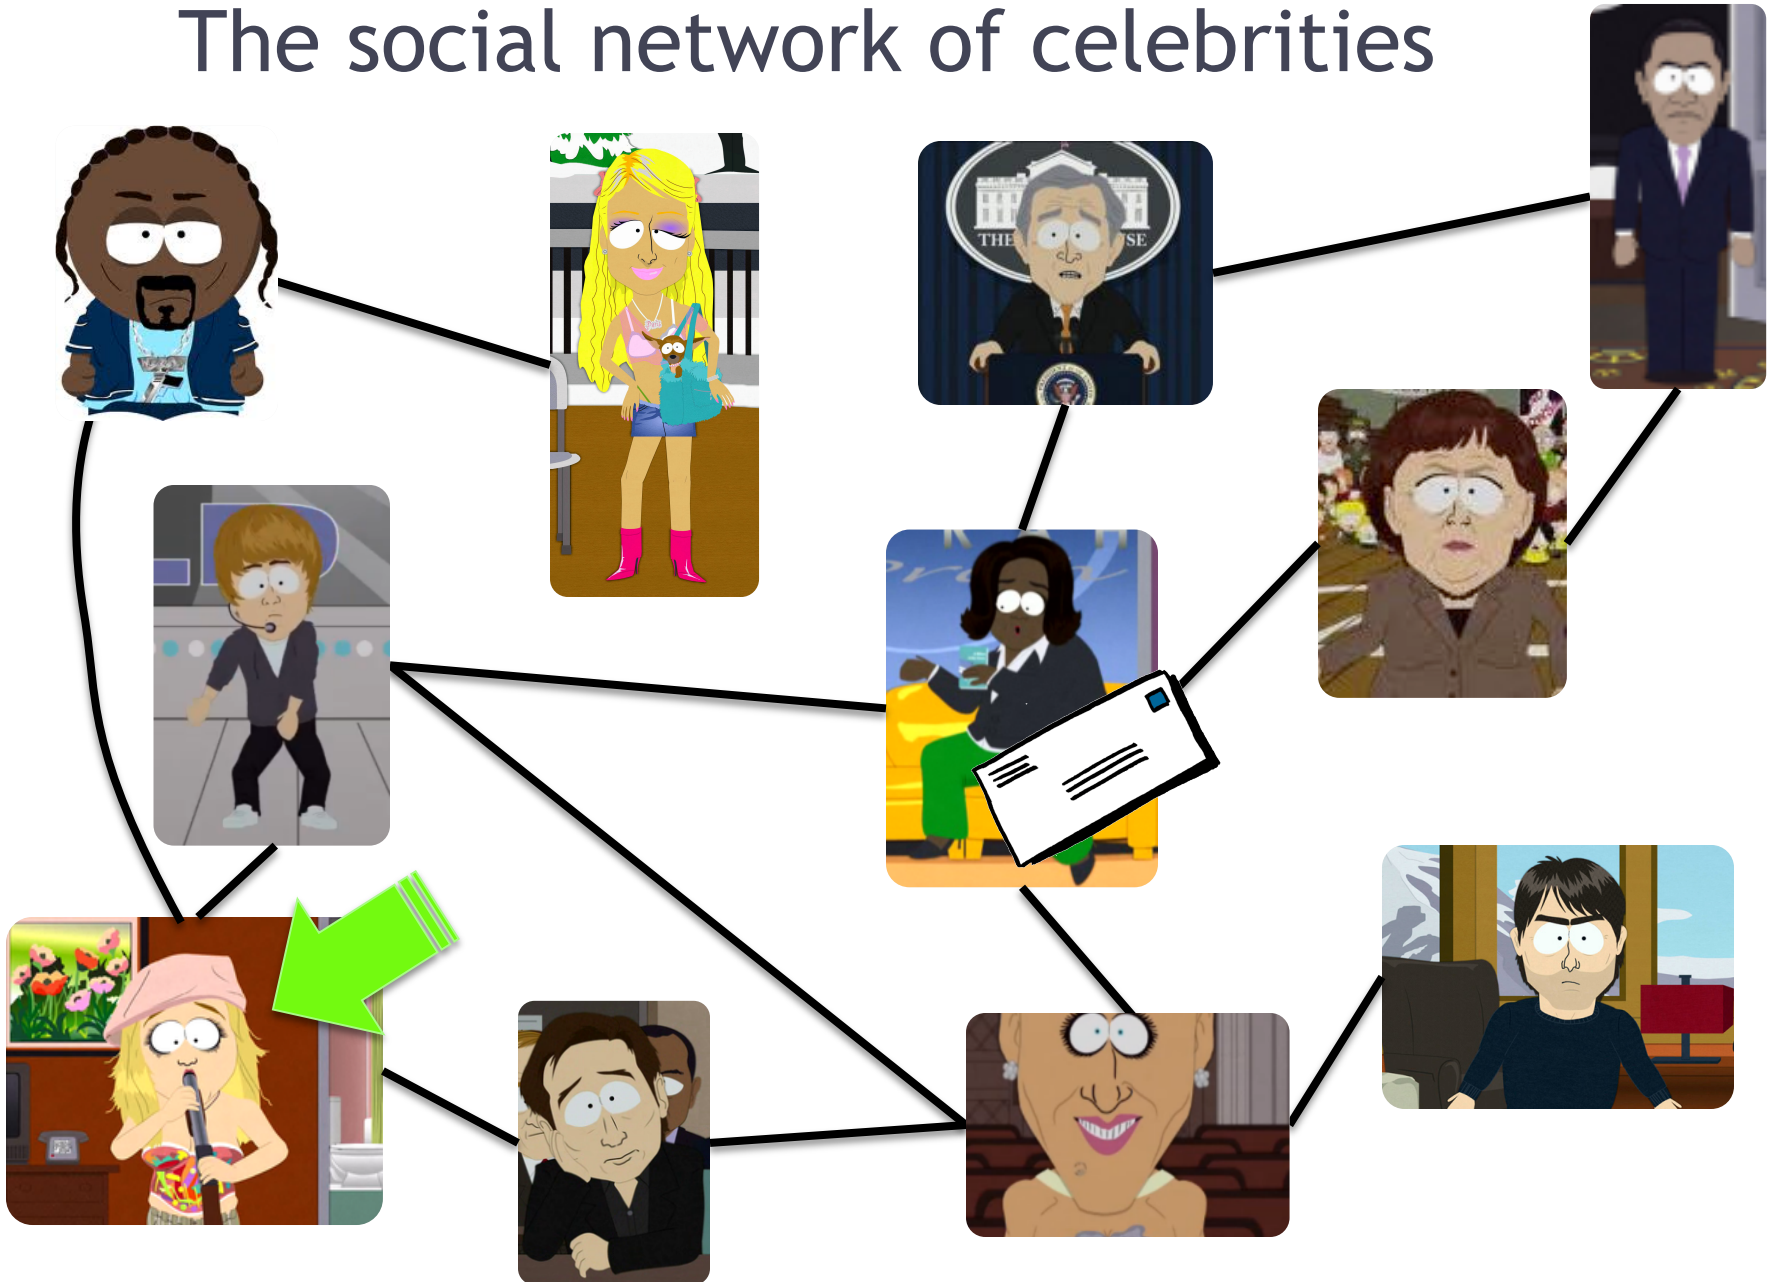

The social network of celebrities

The notion of the small world phenomenon

- Milgram's experiment from the 1960's
 - Given: Social network
 - Idea: How many jumps are needed to reach a random person?
 - Starters: Random people from Nebraska
 - Target: Person, who lived in Massachusetts and worked in Boston
 - Known: Basic information about the target
 - Rule: Send to a people known on first name basis
- Routing using only local information and simple facts
- Routing works!
... and uses always very short paths

Results from Milgram's experiment

- Chain: between 2 and 10 intermediate acquaintances
- Median: 5 intermediates
- Conclusion: Any person appeared to be reachable in just 6 jumps

Results from Milgram's experiment

- Chain: 2 to 10 intermediate acquaintances
- Median: 5 intermediates
- Conclusion: Any person appeared to be reachable in just 6 jumps

REUNION

SIX degrees of separation

A chance encounter would
change their lives forever.

Six Degrees of Kevin Bacon

The Oracle of Bacon:

Six Degrees of Kevin Bacon

The Oracle of Bacon

Importance

- Indicative of the underlying structure of modern social networks
- In what other context:
 - infectious disease spreading
 - computer virus transmission

Observation from Milgram's experiment

- Decisions people take for selecting routes are overwhelmingly categorical in nature
- Categories are based on different factors like:
 - occupation, location, ethnicity

Consider a set of categories
... in the scenario of a social network
of celebrities

Part 2

Definitions and routing algorithm

Definitions:

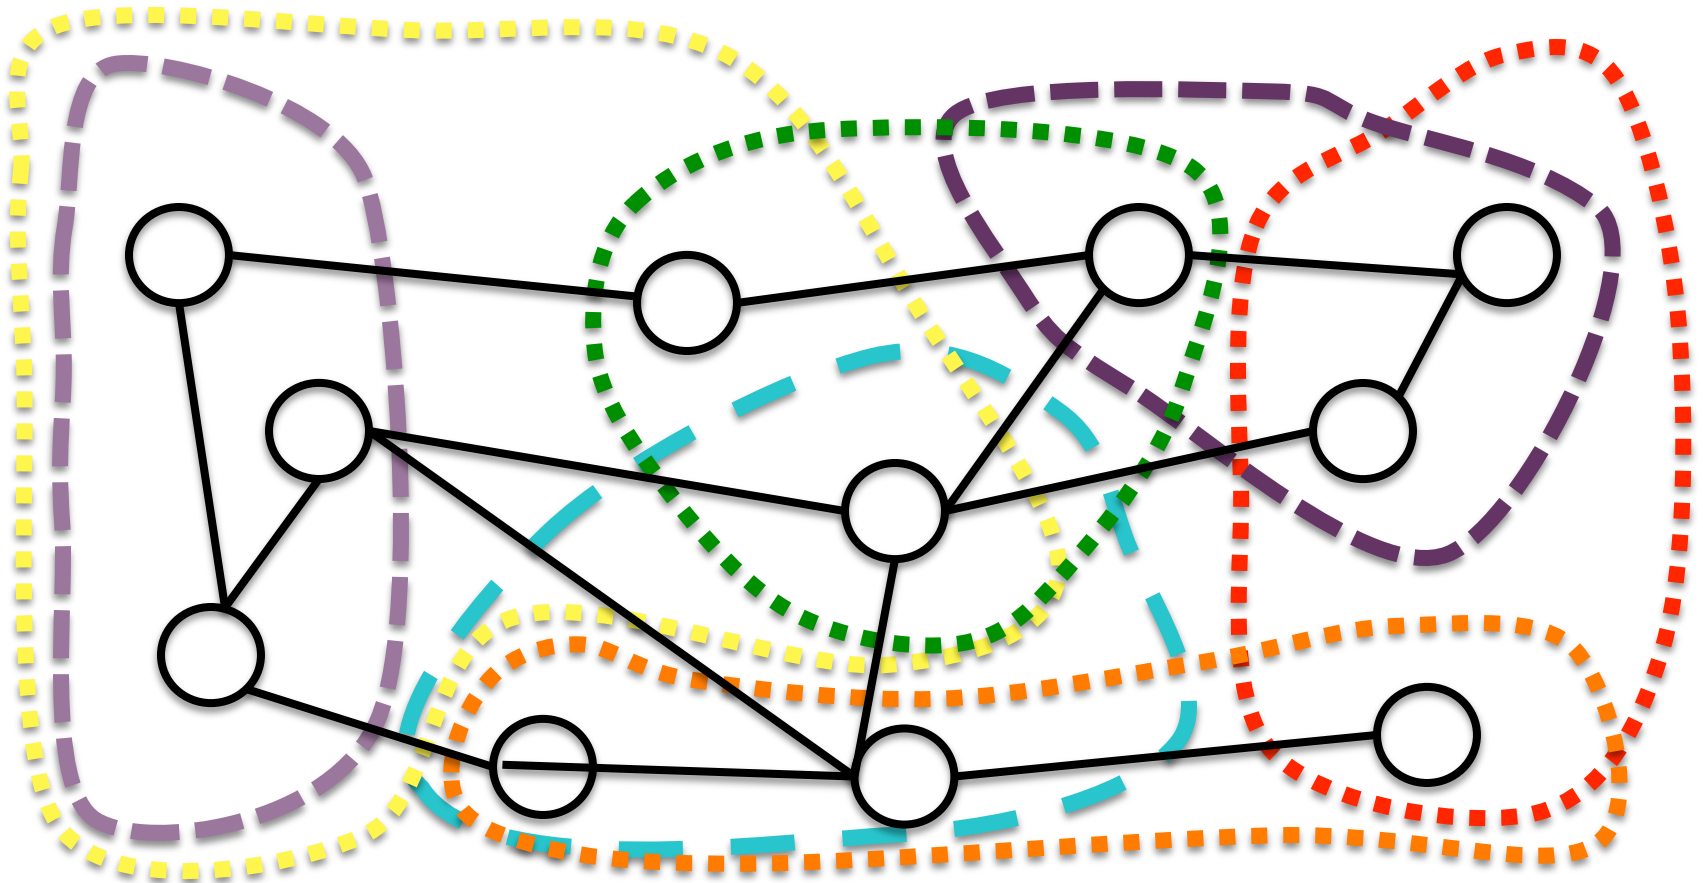

- Collection of categories: $\mathcal{S} \subset 2^U$

Definitions

- Membership dimension: $\text{memdim}(S) = \max_{u \in U} |\text{cat}(u)|$

where $\text{cat}(u) = \{C \in S \mid u \in C\}$ is the set of categories of a node u

Definitions

- Maximum length of any shortest path:
 $\text{diam}(G) = \max_{s,t \in U} \text{sp}(s,t)$

Definitions

- Maximum length of any shortest path

$$\text{diam}(G) = \max_{s,t \in U} \text{sp}(s,t)$$

Greedy routing algorithm

- The category-based distance function: $d(s, t) = |\text{cat}(t) \setminus \text{cat}(s)|$
- Sending from u to w : forward to a neighbor v that is closer to w than u :
 $d(v, w) < d(u, w)$

Greedy routing algorithm

- The category-based distance function: $d(s, t) = |\text{cat}(t) \setminus \text{cat}(s)|$
- Sending from u to w : forward to a neighbor v that is closer to w than u :
 $d(v, w) < d(u, w)$

Greedy routing algorithm

- The category-based distance function: $d(s, t) = |\text{cat}(t) \setminus \text{cat}(s)|$
- Sending from u to w : forward to a neighbor v that is closer to w than u :
 $d(v, w) < d(u, w)$

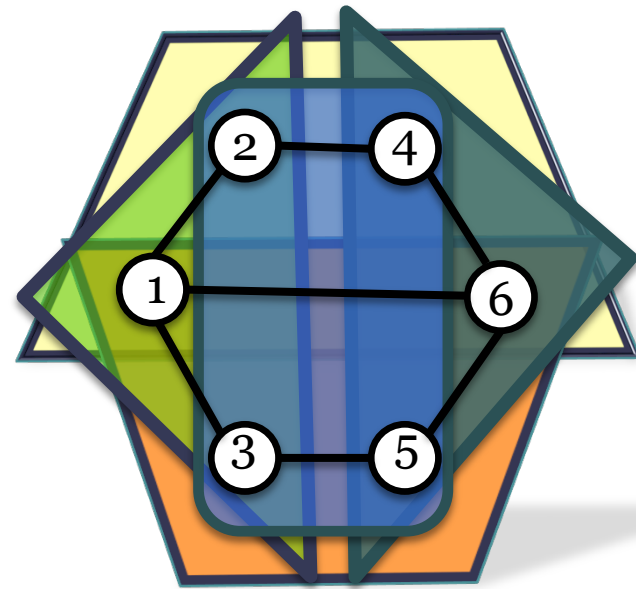

Properties of successful routing

- Internally connected:
(G, S) is internally connected, if for each $C \in S$, G restricted to C is internally connected
- Shattered: A pair (G, S) is shattered if, for all $s, t \in U, s \neq t$, there is a neighbor u of s and a set $C \in S$ such that C contains u and t, but not s.

Examples

Internally connected
&
Not shattered

Shattered
&
Not internally connected

Shattered

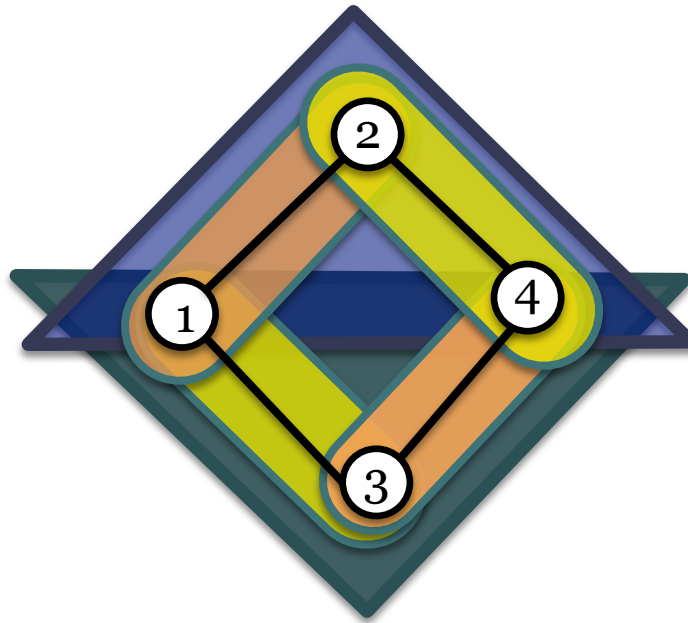

- In order for someone to advance a letter to a target, there must be an acquaintance that shares additional interests with the target.
- **Lemma 1:** If (G, S) is not shattered, Routing fails.

What about routing in trees?

Lemma 2:

If G is a tree, and (G, S) is internally connected and shattered, then Routing is guaranteed to work.

- Not enough for arbitrary connected graphs

Summary of the definitions

- $\text{memdim}(S) = \max_{u \in U} |\text{cat}(u)|$
- $\text{diam}(G) = \max_{s,t \in U} \text{sp}(s,t)$
- Routing: forward to a neighbor v that: $d(v,w) < d(u,w)$
- Internally connected
- Shattered

Part 3

Building categories

Lower and upper bounds

If G and S are a graph and a category system such that Routing works:

- $\text{memdim}(S) \geq \text{diam}(G)$
- $\text{memdim}(S) = O((\text{diam}(G) + \log n)^2)$

Lower bound of the cognitive load

- Lemma 3:

If (G, S) be a graph and a category system, respectively, such that Routing works for G and S . Then $\text{memdim}(S) \geq \text{diam}(G)$

Routing in a graph as path

- Lemma 4:

If G is a path, then there exists an S s.t. (G, S) is shattered and internally connected with $\text{memdim}(S) = \text{diam}(G)$

Routing in a graph as path

- Lemma 4:

If G is a path, then there exists an S s.t. (G, S) is shattered and internally connected with $\text{memdim}(S) = \text{diam}(G)$

Routing in a binary tree

- Lemma 5:

If G is a binary tree, then there exists an S s.t. (G, S) is shattered and internally connected with: $\text{memdim}(S) = O(\text{diam}^2(G))$

Why $\text{memdim}(S) = O(\text{diam}^2(G))$?

For $v \in U$: $u \in \text{ancestors}(v)$

$\Rightarrow v \in S_u$ and v belongs to $O(\text{height}(u))$ sets of L_u and R_u

$\Rightarrow v$ belongs to $O(\sum_{u \in \text{ancestor}(v)} \text{height}(u))$ sets

$\Rightarrow O(\text{diam}^2(G))$

Converting a n-node rooted tree

- Lemma 6:

Let T be an n -node rooted tree with height h . We can embed T into a binary tree such that the ancestor-descendant relationship is preserved, and the resulting tree has a height $O(h + \log n)$

Upper bound of the cognitive load

Theorem:

If G is connected, there exists S s.t. Routing works and $\text{memdim}(S) = O((\text{diam}(G) + \log n)^2)$

- Compute a low-diameter spanning tree T of G $\xrightarrow{\text{BFS}}$ $\text{diam}(T) \leq 2\text{diam}(G)$
- Arbitrary root T and embed T into a binary B
with height $O(\text{diam}(T) + \log n)$, by Lemma 6
- $\text{diam}(B) = O(\text{diam}(T) + \log n)$
- By Lemma 5 $\longrightarrow \text{memdim}(S_B) = O((\text{diam}(T) + \log n)^2)$
- From S_B to S_T and $\text{memdim}(S_T) \leq \text{memdim}(S_B) = O((\text{diam}(T) + \log n)^2)$
 $\longrightarrow \text{memdim}(S) = O((\text{diam}(G) + \log n)^2)$

Summary

- Arbitrary graph: $\text{memdim}(S) \geq \text{diam}(G)$
- Path: $\text{memdim}(S) = \text{diam}(G)$
- Binary tree: $\text{memdim}(S) = O(\text{diam}^2(G))$
- From arbitrary to binary tree: height of $O(h + \log n)$
- Arbitrary graph: $\text{memdim}(S) = O((\text{diam}(G) + \log n)^2)$

Thank you!
